(57) **ABSTRACT**

A humidifier includes a housing with a substantially open top portion. Water can be added to the humidifier by pouring the water into a water reservoir through an open top. The water is pumped from the water reservoir to an upper portion of the humidifier where it is dispersed into the environment by a flow of air. The humidifier may include both an ultrasonic nebulizer and a heater to provide a warm mix of cool mist and hot vapor. Alternatively, a warm mist can be provided by dispersed water from an ultrasonic nebulizer in combination with warm air. The humidifier may also solely provide a cool mist from an ultrasonic element, or the water can be dispersed using a wicking filter.

**COMBINATION WARM AND COOL MIST  
HUMIDIFIER****CROSS REFERENCE TO RELATED  
APPLICATION**

This application is a divisional of U.S. patent application Ser. No. 12/936,483, filed Jan. 24, 2011, now U.S. Pat. No. 8,827,247, which is a 371 of PCT/US2010/43500, filed Jul. 28, 2010, which claims priority to U.S. Provisional Patent Application Ser. No. 61/229,133, filed Jul. 28, 2009, all of which are incorporated by reference herein.

**FIELD OF THE INVENTION**

The present invention relates generally to humidifying devices, and more specifically to humidifying devices with an open top through which a tank may be filled with water.

**BACKGROUND OF THE INVENTION**

Portable humidifying devices, or humidifiers, are used to moisturize the ambient air in a room, most commonly, a single room of a home. Different types of humidifiers are available in both the warm and cool mist varieties. Evaporative humidifiers, or wick humidifiers, utilize a reservoir of water, from which the wick draws moisture, and a fan which forces air through and/or past the wick, thereby picking up moisture as the air is directed through a spout or vent into the room. Ultrasonic humidifiers utilize nebulizers or ultrasonic transducers, a metal diaphragm vibrating at ultrasonic frequency, to cause a fog or mist formed of small water droplets to rise from the surface of a reservoir containing the transducer and out of a directed opening into the room. Similarly, impeller humidifiers break water into small droplets through a rotating disc that directs the water through a diffuser. Because evaporative, ultrasonic and impeller humidifiers do not heat the water, they are commonly referred to as cool mist humidifiers.

Vaporizers or steam humidifiers boil water and release the steam through a spout or vent into the room. However, due to the high temperatures of the steam ( $>100^{\circ}\text{C}.$ ), it is usually cooled somewhat before being released into the room. Typically, this is done by mixing it with cooling air from a fan to create a warm mist that is safe to users. The cooling air is usually mixed with the steam in a pathway leading to the directed opening into the room to ensure that it is sufficiently mixed and contains no "hot spots." The smaller the opening into the room, the more it is mixed and the safer the resultant warm mist. Such so-called "warm mist" humidifiers do not produce a true warm mist because the steam is mixed with cooling air that is not humidified, reducing both output and efficiency. To increase output, the steam is superheated, thus further increasing the risk of getting burned.

However, humidifiers having a combination of warm and cool mist do not typically boil the water. Rather, these combination humidifiers merely heat the water, usually in a connecting tube extending to the nebulizer.

Warm mist humidifiers, though typically consuming more power, also purify the mist through boiling to kill bacteria in the water, while cool mist humidifiers must be cleaned regularly to prevent the accumulation of bacteria and contamination of the air caused by the projection of said bacteria with the mist. Regardless of type, most humidifiers utilize a removable and fillable water tank and a housing with a directed opening, or output vent, which serves to mix and concentrate the mist into the room such that it is projected

2

with sufficient velocity for the droplets to spread apart and humidify a larger volume of the air in the room, not just the air near the humidifier.

**SUMMARY OF THE INVENTION**

Creating a "true warm mist" through the combination of cool mist and steam, or warm mist, increases efficiency and output since the steam is not mixed only with relatively dry cooling air, but also with cool mist created by an ultrasonic transducer. The mist should sufficiently mix to achieve a substantially uniform, safe temperature. While forcing the mist through a small directed opening or vent is an effective mixing mechanism, spreading the mist through a large open top portion of the humidifier while maintaining a high output is more aesthetic (creating a spa look and feel) and distributes the mist evenly into a larger area of the room. Because nebulized mist does not rise as steam does, a mixing plenum in combination with air flow facilitates a fuller mixing, and therefore a more "true warm mist," before rising through the open top portion. Moreover, because constantly removing and replacing a water tank for refilling can become rather arduous, a humidifier which is fillable by merely pouring water into an open top portion makes the humidifier more convenient to use.

In an embodiment, the present invention provides a combination warm and cool mist humidifier having a housing with a substantially open top portion. The housing has an inner wall and an outer wall and an air gap between the inner and outer walls. Each of the inner and outer walls includes at least one vent. A main water reservoir within the housing is fillable by providing water to the substantially open top portion. A level engine deck is disposed above a bottom of the main water reservoir and an impeller is configured to pump water from the main water reservoir to an overflow chamber of the engine deck. The engine deck includes a heating reservoir having at least one heating element disposed therein and a nebulizing chamber having at least one ultrasonic transducer disposed therein. An engine chamber is disposed adjacent the water reservoir and below the engine deck and includes at least one motor for driving the impeller and a fan disposed adjacent the at least one vent of the outer wall of the housing so as to draw air into the air gap and through the at least one vent of the inner wall of the housing.

**BRIEF DESCRIPTION OF THE DRAWINGS**

The foregoing and other features of the present invention will be more readily apparent from the following detailed description and drawings of illustrative embodiments of the invention in which:

FIG. 1 is a perspective view of a humidifier in accordance with an embodiment of the present invention showing the components of the engine deck;

FIG. 2 is a perspective view of a humidifier in accordance with the embodiment of FIG. 1 showing a shield over the engine deck;

FIG. 3 is a top view of the interior of a humidifier in accordance with the embodiment of FIG. 1;

FIG. 4 is a sectional view of the humidifier of FIG. 2 taken along line A-A;

FIG. 5 is a perspective view of a humidifier in accordance with an embodiment of the present invention including a baffled cover;

FIG. 6 is a schematic representation of another embodiment of a humidifier;

3

FIG. 7 is a cross-sectional side view of another embodiment of a humidifier;

FIG. 8 is a front view of the humidifier of FIG. 7

FIG. 9 is a cross-sectional front view of the humidifier of FIG. 7;

FIGS. 10-12 illustrate various weep hole configurations in accordance with an embodiment of the invention;

FIG. 13 is a top view of another embodiment of a humidifier;

FIG. 14 is a cross-sectional side view of the humidifier of FIG. 13; and

FIG. 15 is a cross-sectional front view of the humidifier of FIG. 13.

Like reference numerals are used in the drawing Figures to connote like components of the humidifier.

#### DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Referring to FIG. 1, a humidifier 10 in accordance with an embodiment of the invention has a substantially rectangular housing 100 with a substantially open top portion 128. The main water reservoir 12 of the humidifier 10 is disposed within the housing 100 below the open top portion such that the water reservoir 12 is open to the atmosphere at the top. Accordingly, the humidifier 10 may be top-filled to provide water to the main water reservoir 12. A groove 14 in the bottom 13 of the water reservoir 12 provides water to an impeller 16 which draws the water up through a tube 18 to an overflow chamber 22 of a substantially level engine deck 20 (FIGS. 3 and 4). The overflow chamber 22 maintains the level of water at the engine deck 20 by allowing excess water to flow back into the water reservoir 12 via an overflow opening 24. Additionally, the overflow chamber 22 may also demineralize the water for a cleaner operation, for example, by providing a filter or a chemical for demineralization in the overflow chamber 22. From the overflow chamber 22, the water flows through a first path 26 to a heating reservoir 30 where a heating element 32 boils the water contained therein. From the heating reservoir 30, the water then flows to a nebulizing chamber 40 via a second path 36. The nebulizing chamber 40 includes an ultrasonic transducer 42 for providing a cool mist. An additional path extending from the nebulizing chamber 40 to the main water reservoir 12 may also be provided as a return path. In an alternative embodiment, the water may flow from the overflow chamber 22 to each of the heating reservoir 30 and nebulizing chamber 40 directly. In such an embodiment, the flow can be controlled such that water flowing back into the water reservoir 12 is not heated.

Referring to FIGS. 1-4, the engine deck 20 is provided above and adjacent to the main water reservoir 12 with a sidewall 44 extending upward from the bottom of the main water reservoir 12 to the engine deck 20. The sidewall 44 also serves to insulate an engine chamber 118 contained within the housing 100 adjacent the main water reservoir 12 and below the engine deck 20. The sidewall 44 may be inclined toward main water reservoir 12 to help direct any overflow water and may also include a recessed portion for the impeller 16. This inclined sidewall 44 can reduce or eliminate sounds generated by splashing and dripping as the water returns to the water reservoir 12. Preferably, the housing 100 includes at least an outer wall 102 and an inner wall 104 with an air gap 106 defined therebetween. The inner wall 104 is attached or integral to the engine deck 20 such that the engine chamber 118 has pathways to the air gap 106. The engine chamber 118 is sealed within the housing 100 from the main water reservoir 12 and the engine deck 20 so as to prevent water from entering

4

into the engine chamber 118. Preferably, the air gap 106 is provided along all four sides of the housing 100. In one embodiment, the air gap 106 is also provided in the base section of the housing 100 extending below the main water reservoir 12.

At least one motor 120 is provided in the engine chamber 118. The motor 120 preferably utilizes a magnetic drive with first and second output shafts 122, 124 at opposite sides thereof. In this manner, the impeller 16 can be attached to the first output shaft 122 and a fan 126 can be attached to the second shaft 124 so as to drive both the impeller 16 and the fan 126 by the same motor 120. Preferably, the first output shaft 122 runs to drive a first magnet 123 disposed within the engine chamber 118. The first magnet 123 is coupled to drive a second magnet 125 disposed on the other side of sidewall 44. The second magnet 125 is connected to the impeller 16 so as to drive it. The magnetic coupling of the first and second magnets 123, 125 also serves to maintain the impeller 16 on a bearing 121 which prevents the impeller 16 from becoming unstable and causing noise when the main water reservoir 12 reaches a low fill level. The magnetic coupling also ensures that no opening to the engine chamber 118 is created through which a leak could form. Such an arrangement saves space, increases efficiency and decreases manufacturing costs since only one motor 120 is required. However, it is also possible for the fan 126 and the impeller 16 to be separately driven. The fan 126 also serves to cool the engine chamber 118, including motor 120 so that it operates more efficiently and does not overheat.

The fan 126 is arranged adjacent the outer wall 102 of the housing 100 in a region containing intake vents 108. The intake vents 108 may be provided with a filter to purify the air as it enters the housing 100. The motor 120 drives the fan 126 in order to pressurize the engine chamber 118 and force air into the air gap 106. The air travels between the outer and inner walls 102, 104 of the housing 100 (i.e., through air gap 106) and exits into the interior of the humidifier 10 through one or more output vents 110 disposed in the inner wall 104. Preferably, output vents 110 are provided in the inner wall 104 on each side of the housing 100 at the open top portion 128, or between the engine deck 20 and the open top portion 128, in order to mix and evenly distribute the warm mist rising from the heating reservoir 30 and cool mist rising from the nebulizing chamber 40. The airflow provided by the output vents 110 also serves to pressurize the interior of the humidifier 10 so that the combined mist rises substantially uniformly from the open top portion 128. In this manner, a substantially uniform output of mist at a substantially uniform temperature is provided throughout the open top portion 128 of the humidifier 10. Preferably, the temperature of the air and combined mist exiting through the open top portion 128 is in the range of 110° F. to 130° F. (43.3° C. to 54.4° C.).

The engine deck 20 is covered by a shield 116 to prevent water from falling onto the engine deck when the humidifier 10 is top filled by a user. Preferably, the shield 116 is inclined downward from the inner wall 104 at the rear of the housing 100 toward the main water reservoir 12. The shield 116 may be a single sloped surface or a series of sloped steps and extends at least slightly beyond the sidewall 44. The shield 116 may be attached to the housing 100, but is more preferably removably arranged on supports 114 to allow access to the engine deck. In the embodiment shown in FIGS. 1-4, the shield 116 includes sloped steps with air gaps between the steps to allow the mist to pass therethrough. For this reason, output vents 110 are provided behind the steps between the engine deck 20 and the shield 116. The humidifier 10 can be top filled with water anywhere through the open top portion

128 and the shield 116 directs the water away from the engine deck 20 and into the main water reservoir 12. Accordingly, the humidifier 10 is easy to fill without affecting its operation as a substantially even level of water at the engine deck is maintained. In conjunction with the airflow from the output vents 110, the shield 116 also helps to direct condensation forming on the bottom thereof away from the engine deck 20. In addition, the bottom of the shield 116 may also include ribs to direct water and prevent condensation from falling into the heating reservoir 30 or the nebulizing chamber 40.

The main water reservoir 12 includes a shut-off device 48 which may be, for example, a hollow tube 50 having a floating foam donut 52 disposed thereabout. The hollow tube 50 includes a thin metal magnetic reed switch 54 disposed at a predetermined minimum fill level at or near the bottom of the main water reservoir 12. As water in the main water reservoir 12 is used up, the donut 52, which also contains a magnet, floats downwards with the level of water toward the reed switch 54. Upon reaching the reed switch 54, the magnet in the donut 52 shuts off the reed switch 54 which is connected to the power supply of the humidifier 10 to prevent the heating element 32 from burning out. In addition to cutting off power to the humidifier 10, the reed switch may also be used to cause an indicator light 140 on the housing 100 to be lit and to indicate that the unit is out of water. Further, additional reed switches 54 may also be provided at predetermined heights in the hollow tube 50 to indicate one or more fill levels. As the main water reservoir 12 is filled, the donut 52 will float upwards toward a reed switch 54 and, upon reaching one of the predetermined heights, will turn on the reed switch 54 which is connected to an indicator light 140 on the housing 100 to indicate to a user that a fill level (for example, a maximum fill level) has been achieved so that the humidifier 10 is not overfilled. Alternatively, a low voltage system with small electrodes may be substituted for the reed switches 54. In such an embodiment, a circuit can be completed by water contacting the electrodes thereby causing the indicator light 140 to indicate to the user that a desired fill level has been achieved. As another alternative, or in addition, the humidifier may include a float switch to shut off the humidifier when it is empty.

Alternatively or in addition, one or more shut-off devices could be provided on the engine deck 20. Accordingly, such a shut off device could directly measure the amount of water being received by either or both of the heating element 32 or ultrasonic element 42. Thus, the vaporizing engines could be shut off if they are not receiving water, regardless of the amount of water in the tank (for example, if there were a problem with the impeller 16).

Other fill level indicators, such as a viewing window in the housing 100 with graduations, may also or alternatively be provided to indicate the overall level of water in the main water reservoir 12. Likewise, at least a portion of the walls of the housing 100 could be transparent and could be provided with cascading water falling to the level of water in the main water reservoir 12 so as to create a water wall effect.

The housing 100 may be any of a number of shapes, such as square, circular or oval and may be formed from one or more of plastic or metal. The base of the housing 100 may be provided with feet 129, which may also be adjustable in height, to keep the humidifier 10 stable and level. Additionally, a decorative wall or covering with various patterns and colors may be provided around the outside of the housing 100. Further, the housing 100 may include lighting, for example, light-emitting diodes (LEDs) within the humidifier 10 or about the open top portion 128 to accent or "light up" the rising mist in various colors. Where LEDs are provided, it is

possible to also shunt the air provided across the nebulizing chamber 40 so as to create a swirling glow effect.

While it is preferable to arrange the main water reservoir 12 on one side of the housing 100 and the engine chamber 118 on the other in order to efficiently make use of the internal space of the humidifier 10, other configurations are also possible. For example, the engine chamber 118, with the engine deck 20 disposed thereabove, could be sealingly, centrally disposed in the housing 100, with the main water reservoir 12 surrounding the engine deck 118. To draw air into the housing 100, a drive shaft could be attached the first output shaft 122 extending through or beneath the main water reservoir 12 to a fan 126 disposed in a widened region of the air gap 106 adjacent intake vents 108.

The impeller 16 may be continuously or periodically operated to provide water to the engine deck 20 through tube 18. Preferably, the impeller 16 and the fan 126 are both continuously run by the motor 120. Additionally, by providing a continuous supply of water at higher volumes to the overflow chamber 22, a waterfall effect through the overflow opening 24 and/or overflow spout 23 can be achieved. The overflow chamber 22 preferably demineralizes the water, for example, by providing one or more filters disposed between ribs at an inlet and/or an outlet of the overflow chamber 22.

Because the engine deck 20 is substantially horizontally level and the overflow chamber 22, the heating reservoir 30, the nebulizing chamber 40 and the first and second paths 26, 36 are formed as recesses therein, the water is provided at substantially the same level to the foregoing components of the engine deck 20 to facilitate a level, controlled rate of flow. Instead of recesses, the first and second paths 26, 36 may alternatively be tubes or other types of passages. From the overflow chamber 22, the water flows through the first path 26 to the heating reservoir 30. The heating reservoir 30 includes at least one heating element 32, for example, a centrally disposed, traditional resistance heating element, which boils the water in the heating reservoir 30. The first path 26 is preferably a tortuous or serpentine path so as to tune the flow of water to the heating reservoir 30. Similarly, the second path 36 extending from the heating reservoir 30 to the nebulizing chamber 40 is also preferably a tortuous or serpentine path to control the flow rate and to cool the water before it reaches the nebulizing chamber 40. Due to a relatively small cross sectional area of the first and second paths 26, 36 relative to the heating reservoir 30 and the controlled flow of the water provided by the tortuous or serpentine path, the convective losses from the heating reservoir 30 are reduced, and thus, boiling efficiency is increased. In conjunction with the tuned flow of water from the first path 26, the heating reservoir 30 is able to consistently produce a high output of steam. A high output of humidifying mist is produced by the humidifier 10 when the high output of steam is mixed with the cool mist emitted from the nebulizing chamber 40 by the at least one ultrasonic transducer 42 vibrating therein at ultrasonic frequencies. The arrangement of the heating reservoir 30 and the nebulizing chamber 40 on the engine deck 20 (as illustrated, for example in FIG. 1) could be switched, so that the water reaches the nebulizing chamber 40 before it reaches the heating reservoir 30. When cooler water is provided to a nebulizer the mist can have the tendency to condense onto a cool floor. Moreover, because the water is purified by boiling in the heating reservoir 30 (killing approximately 96% of the bacteria) both the warm and cool mist are purified and the bacteria is prevented from becoming suspended in the ambient air. Nevertheless, it is possible to provide water to the nebulizing chamber 40 directly from the overflow chamber 22, in particular in a cool mist embodiment where the heating res-

ervoir **30** is not provided. Likewise, water could also be provided directly to the heating reservoir **30** as well. Alternatively, as described above, two separate paths could extend from the tube **18** along the engine deck **20** to the heating element **32** and ultrasonic element **42**. Accordingly, the warm mist from the heating element **32** and cool mist from the nebulizer **42** would mix before exiting the humidifier **10**.

The humidifier **10** may also utilize ultraviolet disinfection to make the water germ-free. One way to accomplish this would be to provide an ultraviolet lamp adjacent to the first path **26**. Other methods of providing ultraviolet disinfection are described in the commonly owned U.S. Pat. No. 7,513,486, the entire contents of which is incorporated herein by reference.

In one embodiment, the heating element **32**, the ultrasonic transducer **42** and the motor **120** are connected to the same standard power supply, but have separate controls for each on a controller **130** connected to a power supply PS, for example, a battery or a standard AC source through a standard power cord **138**. For example, a transducer control **132**, a heating element control **134** and a fan speed control **136** may be provided to separately control the ultrasonic transducer **42**, the heating element **32** and the fan **126**, respectively. In this way, it is possible for the user to get only cool mist from the nebulizing chamber **40** or to get only warm mist from the heating reservoir **30**. Additionally, the temperature of the combined mist may be adjusted by varying the power levels provided to the heating element **32**, the ultrasonic transducer **42**, and/or the fan **126**. Further, a temperature sensor **150** may be provided and coupled with the controller **130** to automatically provide the proper power levels at all times. A humidity sensor **152** may be provided near or at the open top portion **128** and/or outside the housing **100** to sense the level of humidity and send a signal to the controller **130** to throttle back the power levels when it nears a predetermined humidity level. In this way, it is possible to avoid the non-uniform on/off cycling of typical humidifying devices. The controller **130** may be a proportional-integral-derivative (PID) controller communicating with the humidity sensor **152** and/or temperature sensor **150** and using control loop feedback that throttles back power to substantially maintain a predetermined humidity level and/or temperature.

In other embodiments, different models or configurations of the humidifier **10** are provided. For example, the engine deck **20** may contain either the heating reservoir **30** only or the nebulizing chamber **40** only to provide warm mist or ultrasonic/cool mist models, respectively. In these cases, the overflow chamber **22** would extend via a first path **26** to either the heating reservoir **30** or the nebulizing chamber **40**, depending on the model, and a second path could lead back to the main water reservoir **12**. The humidifier **10**, including the combined mist, the warm mist and ultrasonic/cool mist models, may also be provided with an evaporative wicking filter and/or as an evaporative model.

To provide such an evaporative model, a wicking filter **162** (shown for exemplary purposes in FIG. 1 with dashed lines) having a supporting grill **160** is provided on the engine deck **20** over the overflow chamber **22**, or a separate reservoir, to draw water therefrom. The wicking filter **162** is typically formed from slit and expanded paper provided in multiple layers. Air is then forced orthogonally through or past the wicking filter **162** from the pressurized engine chamber **118** through output vents **110** provided in the engine deck **20** below the wicking filter **162** and/or on the inner wall **104** of the housing **100**. Alternatively, the airflow may be reversed such that it is drawn into the humidifier through the wicking filter **162**. Preferably, the wicking filter is arranged horizon-

tally or at an incline relative to the engine deck **20** so as to maximize its surface area facing the substantially open top portion **128**. In this arrangement, the wicking filter **162** pulls water in horizontally through its layers from the overflow chamber **22** and/or one or more additional chambers. A gutter **161** may be provided around the periphery of the wicking filter **162** to direct water dripping therefrom back to the main water reservoir **12**, and the wicking filter **162** may be inclined toward the gutter **161**. Providing moisture to at least a portion of the cooling air through the wicking filter **162** further provides the advantage of increased humidity levels which can be attained. In addition, a purely evaporative model of the humidifier **10** could be provided by leaving out the heating chamber **30**, the nebulizing chamber **40** and first and second paths **26**, **36** or by shutting them down via the heating element control **134** and the transducer control **132**.

Referring to FIG. 5, a cover **60** which may also serve as a mixing plenum **61** is provided at the open top portion **128** of the humidifier **10**. The cover **60** is preferably removable and supported by a ledge **112** at or near the top of the housing **100** (as shown, for example in FIG. 1). The cover **60** includes a plurality of openings or baffles **62** throughout, for example, in a grid pattern. The baffles **62** may be of various size and shape, such as rectangular or circular. The baffles **62** and the cover **60** facilitate a more uniform flow of mist through the open top portion **128** by further spreading and mixing the warm and cool mist and providing directed openings for the combined mist. The cover **60** may also include spouts and/or paths which may be, e.g., aqueduct paths for retaining water on the surface thereof. Preferably, a mixing plenum **61**, which may have a similar configuration to the cover **60**, or could consist of other shapes, such as tapered, and may include a plurality of spouts and/or tortuous paths, is also provided below the cover **60** for further mixing the cool mist and steam prior to it rising out from the top of the humidifier **10**. Additionally, the cover **60** provides a support surface for various additional features for aesthetics and/or increased functionality. For example, a bed of smoothed stones **64**, or polished pebbles, may be provided on the cover **60**. In addition to making the humidifier more aesthetically pleasing by giving a natural spa-like look and feel, the smoothed stones **64** also serve multiple functions. First, the stones **64** help to further mix and distribute the warm mist as it travels through the stones **64** and out of the top of the humidifier **10**. Second, the stones **64** are warmed and wetted as mist rises therethrough (and also wetted when the humidifier **10** is top filled by the user), thereby providing additional heat and moisture to the rising mist through convection and evaporation. Additionally, the stones **64** may be provided with an aromatic oil to provide a pleasing and fragrance to the room. Further, a medicated inhalant may also be provided at the cover **60** for therapeutic purposes. The open top portion **128** and the even distribution of mist at a substantially uniform and safe temperature makes it easy for a user to utilize the humidifier **10** for therapeutic purposes since it creates a larger area for the user to breathe in the medicated inhalant without fear of being burned. Similarly, wood chips, pellets or blocks could also be provided on the cover **60** serving like functions to the stones **64**.

FIG. 6 shows a schematic illustration of another embodiment of a humidifier **200** in accordance. Humidifier **200** illustrates additional features of a humidifier that may be implemented in accordance with the invention. These features can be combined with any of the features described above with respect to humidifier **10**. Humidifier **200** includes a water feature **202**, in the form of a shallow waterfall. The water feature **202** is an attractive addition of the humidifier **200** and functionally delivers water pumped from the main water res-

ervoir **212** to the engine deck **220**. The water feature **202** may include one or more steps **204** that the water cascades over as it flows down the water feature. The water is pumped up to the water feature **202** from the main water reservoir **212** with an impeller **216**. The impeller **216** is driven by a motor and may be connected thereto magnetically as discussed above with respect to humidifier **10**. Although the impeller **216** and fan **226** are shown at opposite sides of humidifier **200**, these elements may be configured more closely so that they can be driven by a single motor, as discussed above. In operation, the water is driven up to the water feature **202** through a tube **218**, as shown by the solid arrows in FIG. 6. The water then flows down the water feature **202** until it falls into an overflow chamber **222** on the engine deck **220**. The engine deck **220** is equipped with a nebulizing chamber **240**, which receives water from the overflow chamber **222**. An ultrasonic transducer **242** disperses water from the nebulizing chamber **240** into the air above engine deck **220** forming a cool mist. Excess water that is not immediately converted into a mist falls from the overflow chamber **222** back into the main water reservoir **212**.

Use of the impeller **216** to cycle water over the water feature **202** and onto the engine deck **220** where it contacts the ultrasonic transducer **242** allows the main water reservoir **212** to be open to atmospheric pressure. In contrast, the water in most humidifier tanks is held in the tank by a vacuum. This open type of system also allows the amount of water held in the nebulizing chamber **240** to be controlled very precisely by using the overflow chamber **222** to distribute excess water back to the main water reservoir **212** so that the ultrasonic transducer **242** always has an appropriate amount of water.

The cool mist formed by the ultrasonic transducer **242** is mixed with air in a mixing chamber **230** above the engine deck **220**. The air is delivered to the mixing chamber **230** from a duct **232** as the result of a fan **226** disposed in an engine chamber **208** below the engine deck **220**. The fan **226** pressurizes the air in the mixing chamber **230**, causing it to flow up and out of the humidifier **200** through a cover and stones **214**.

The humidifier **200** may be operated in the above-described manner to produce humidification in the form of a cool mist. Alternatively, a heating element **234** may be included in the duct **232** to warm the air before it is mixed with the mist. As a result, the heated air heats the dispersed water producing a warm mist. The warm mist then rises through the cover **206** and stones **214** creating a spa effect. In the illustrated embodiment, the heating element is formed as a wire heater that is wound helically within the duct between the fan **226** mixing chamber **230**. Alternatively, the wire heater could be wrapped around the duct **232**. Other embodiments of the heating element are also possible. For example, the heating element **234** may be a PTC element. The heating element **234** could also be coupled to a heat exchanger to increase the efficiency of the delivery of heat to the air. Forming a warm mist by heating the air and mixing the heated air with the cool mist provides certain advantages over the inclusion of a water heater in the humidifier. First, energy from the water heater can transfer to water outside of the heater chamber. Thus, with a water heater, the water in the overflow chamber **222** may be warmed. As a result, this warm water can overflow into the main water reservoir **212**. Thus, over time, all of the water in the system can be warmed, which may be seen as disadvantageous by a user. Moreover, many ultrasonic transducers perform more efficiently with room-temperature water. Thus, heated water will negatively affect the efficiency of the humidifier.

FIGS. 7-9 show another embodiment of a humidifier **300** in accordance with the invention. Humidifier **300** illustrates additional features of the invention, which may be combined with any of the features of humidifiers **10** or **200**. Similar to humidifiers **10** and **200**, humidifier **300** includes an open top **328** which allows the main water reservoir **312** to be filled by pouring water into the humidifier **300** from the top, for example, using a pitcher. From the main water reservoir **312**, the water is pumped up through a tube **318** to an overflow reservoir including a nebulizing chamber **340** on the engine deck **320**. The water is pumped to the engine deck **320** using an impeller **316**, which is driven by a motor **314**.

The engine deck **320** includes a nebulizing chamber **340** in fluid communication with an ultrasonic transducer **342**. The transducer **342** disperses water from the nebulizing chamber **340** into a cool mist in a mixing chamber **330**. The mist is then mixed with pressurized air that is driven into the mixing chamber **330** by a fan **326**. In the illustrated embodiment, the fan is housed in an engine chamber **308** disposed below the engine deck **320**. The fan **326** is driven by a motor which may be the same motor **314** as that which drives the impeller **316**. Alternatively, a separate motor may be used to drive the fan **326**. The fan **326** pressurizes air within the engine chamber **308** which drives the air through a duct **332** into the mixing chamber **330** where it mixes with the mist. As an alternative, air may flow from the engine chamber **308** to the mixing chamber **330** through a port connecting the two chambers. The mist is propelled into the atmosphere by the pressurized air within the mixing chamber **330** through a nozzle **306**. In an embodiment, the nozzle may be rotatable, such that the mist can be directed in a direction as desired by the user.

Excess water pumped to the engine deck **320** overflows from the overflow chamber **340** down a water feature **302** back into the main water reservoir **312**. The water feature **302** of humidifier **300** is configured as a curved slope that flows down to the main water reservoir **312**. The slope **302** curves downward, such that the gradient is shallow at the top and steep at the bottom. The bottom of the slope **302** flows into a funnel **324** that delivers the water back to the main water reservoir **312**. The combination of the slope **302** and the funnel **324** allows the water overflowing from the engine deck **320** to first flow smoothly into a pool formed in the funnel **324** and then be poured into the main water reservoir **312**. The bottom of the funnel **324** has a constricted outlet **348**, which controls the flow rate to the main reservoir **312**. Accordingly, a pool of water is formed in the bottom of the funnel **324**. The curved slope **302** of the water feature allows the water to flow into the pool in the funnel **324** quietly. This prevents a loud splashing sound that would otherwise occur if the water flowed directly into the water reservoir **312** from the overflow chamber **322**. The bottom of the funnel **324** may be positioned low enough that constricted outlet **348** is submerged in the water within the reservoir **312**, or it may be close enough to a surface that a splashing sound is avoided. The constricted outlet **348** may be achieved by a narrow tapering toward the bottom of the funnel **324** or with one or more small openings at the bottom of the funnel.

To prevent the funnel **324** from overflowing, it may include weep holes **350** along a sidewall thereof. The weep holes **350** allow water to drain out of the funnel **324** when the water flow is greater than the amount that can flow through the constricted entrance. Moreover, the weep holes **350** can control the position of the top of the pool within the funnel **324** over a range of different water flow rates. Within a range of flow rates, the water level within the funnel **324** will build until water is flowing out of the weep holes **350**. Accordingly, the

11

weep holes **350** can be positioned at a height that is optimal for reducing splashing noises of the water flowing down the curved slope **302**.

To add further control to the water level in the funnel **324**, a plurality of rows **352** of weep holes may be included in the funnel at different heights. In the illustrated embodiment, the weep holes increase in size from the lowest row to the highest row, as shown in FIG. **10**. This allows greater use of the weep holes **350** for draining water from the funnel **324**, as the water flow rate increases more drastically. The top row **352** of weep holes may be large enough that water will flow out of the funnel **324** at even very large flow rates. For example, if a user pours additional water into the humidifier **300** on the curved slope **302**. Further, the top row **352** of weep holes may include more holes than the lower rows. For example, in FIG. **10**, each row contains one more weep hole than the row below it. In the embodiment shown in FIGS. **8** and **10**, the weep holes are all round. Alternatively, the weep holes may be formed in other shapes, such as ovals or polygons, as shown in FIG. **11**. Moreover, the holes may all be formed in the same shape, as shown in FIG. **10**, or they may have different shapes, as shown in FIG. **11**. Furthermore, the holes may be bored through the side wall of the funnel in a variety of manners to vary the ease of manufacturing or the ability of the holes to drain the water quietly down the side wall of the funnel **324** which is slightly inclined toward the water reservoir. For example, FIG. **12** shows weep holes formed in three different manners. The image on the left shows weep holes that are directed straight through side walls, which simplifies manufacturing. The image in the middle of FIG. **12**, shows weep holes with a curved lower edge on the outer side of the funnel **324**. This would provide exceptionally quiet drainage through the holes. The image on the right shows angled weep holes which may be easy to manufacture and provide quiet drainage.

Humidifier **300** may also include a window **336** on a front surface thereof, as shown in FIG. **8** which allows the user to see the water level of the main water reservoir **312**. A light may also be provided in the vicinity of the window **336** to illuminate the water level. In one embodiment, the constricted outlet **348** may be aimed toward the window **336** within the water reservoir **312**. As a result, air bubbles that are introduced into the water reservoir with water from the funnel **324** may travel to the window **336** and rise along the window creating a "water wall" visual that is pleasing to the user.

FIGS. **13-15** illustrate another humidifier **400** in accordance with the invention. Humidifier **400** illustrates additional features of the invention, which may be combined with any of the features of humidifiers **10**, **200** or **300**. Humidifier **400** includes a wicking filter **462** that disperses water into the air. A water feature **402** drips water onto the filter **462**, which is spread through the body of the filter. Air from a fan **426** is forced up through the filter **426** to distribute the water into the atmosphere around humidifier **400**. The filter **462** may be formed from one or more layers of paper or plastic sheet that is slit at regular intervals and expanded to provide a lattice structure with a large surface area. Similar to humidifiers **10**, **200** and **300**, discussed above, humidifier **400** has an open top **428** so the water reservoir **412** may be filled by pouring water through the open top **428**. The top of the humidifier may include a grating **470** to protect the filter **462** from objects falling into the humidifier **400** and to encourage users to refill the main water reservoir **412** from an open front side **454** of the humidifier **400** that includes a funnel **424**.

From the water reservoir **412**, water is pumped to an upper portion of the humidifier through a tube **418** using an impeller **416**. At the top of the humidifier **400**, the water is guided to one end of a water feature **402** at a rear side **456** of the

12

humidifier **400**. The water flows through a channel **404** across to the front side **454** of the humidifier dripping water through a number of openings **410** in the channel **404** onto the wicking filter **462**. At the front side **454** of the humidifier, the water returns to the water reservoir **412** via the funnel **424**. Similar to that of humidifier **300**, the water feature **402** may lead into the funnel **424** along a curved slope so that a splashing noise is reduced. Moreover, funnel **424** may have a constricted outlet **448** at the bottom to promote the formation of a pool in the funnel, which further silences the movement of the water.

As stated above, the water that is dripped onto the wicking filter **462** is spread throughout the body of the filter which has a large surface area. From the wicking filter **462**, the water is dispersed into the atmosphere by pressurized air within the humidifier **400** as a result of the operation of fan **426**. The fan **426** is driven by a motor **414**, which is housed together with the fan **426** in an engine chamber **408**. Air is propelled by the fan **426** into the inside of the humidifier through a vent **440**. As pressure inside the humidifier builds, the air is forced up through the wicking filter **462**, where it gathers moisture which is then dispersed into the room.

Similar to humidifier **300**, humidifier **400** is configured to adapt to varying amounts of water flow. Accordingly, the channel **404** of the water feature **402** includes dividers **430** that form three separate conduits in the channel **404**. The inner conduit includes one or more openings **410** along its length to distribute a small amount of water to the wicking filter **462** during low water flow levels. Accordingly, the humidifier **400** is able to run for long periods of time when the water flow is low. If the water flow is increased, the water will flow into the outer conduits, where it can be delivered by additional openings **410** to the wicking filter **462** over a larger area of the filter. To further limit the output of the humidifier during low speed operation, the humidifier **400** may include a louver in the air supply plenum to restrict air flow during low speed operation. In such an embodiment, when the humidifier runs at high speed, the air pressure can force the louver to a fully open position. In contrast, when the humidifier runs at low speed, the louver can be partially closed, thereby restricting air flow.

The wicking filter **462** is substantially planar and sits below the grating **470** underneath the channel **404** of the water feature **402**. In operation, the filter **462** is horizontally disposed so that the upward moving air passes through a large cross-section of the filter **462**. Water dripping down onto the center of the wicking filter **462** through the openings **410** in the channel **404** is wicked horizontally outward so that all of the air passing through the filter **462** is able to carry water from the humidifier **400**. The filter is supported in the humidifier by a mesh support **460** that is configured as a thin sheet, such as a screen. Excess water that is not captured by the air flowing through the wicking filter **462** will settle to the bottom of the filter **462** and drip downward.

To control the dripping of the water from the wicking filter **462**, the mesh support **460** is stretched taut in the v-shape with the lowest point **464** in the center. As a result, excess water in the filter will flow to the center and drip in a controlled manner only from the low point **464** of the filter. To utilize this controlled dripping, the humidifier includes a conduit **474** disposed below the wicking filter **462** along the low point **464** of the v-shaped support **460**. To promote capturing of the excess water in the conduit **474**, the conduit **474** may include a central ridge **472** that extends up toward the support **460**. The ridge **472** helps break any surface tension in drops of water hanging down from the filter **462**, thereby ensuring that they fall into the conduit. Similar to the channel **404** of the water feature, the conduit **472** may also have a curved slope

13

toward the front side **454** of the humidifier **400** forming a second funnel to quietly lead water into the reservoir. over-bearing

While the invention has been particularly shown and described with reference to preferred embodiments thereof, it will be understood by those skilled in the art that various changes in form and details may be made therein without departing from the spirit and scope of the invention. Accordingly, the invention is to be limited only by the scope of the claims and their equivalents.

What is claimed is:

**1.** A humidifier comprising:

a housing with a substantially open top portion;

a main water reservoir finable by providing water through the substantially open top portion of the housing;

an engine deck configured to hold water disposed above a bottom of the main water reservoir;

an impeller configured to pump water from the main water reservoir to an overflow chamber of the engine deck;

a heating chamber disposed on the engine deck and having at least one heating element disposed therein;

a nebulizing chamber disposed on the engine deck and having at least one ultrasonic transducer disposed therein; and

an engine chamber disposed adjacent the main water reservoir and below the engine deck, the engine chamber including at least one motor for driving the impeller and a fan, the fan being configured to draw air through the housing so as to carry water vapor produced by the heater and nebulized air into the environment around the humidifier.

14

**2.** The humidifier of claim **1** wherein the engine deck includes first and second paths configured to respectively direct water from the impeller to the heating chamber and nebulizing chamber.

**3.** The humidifier of claim **1** further comprising a control device operable to selectively operate the heating chamber and nebulizing chamber.

**4.** The humidifier of claim **1** further comprising a control device operable to adjust the flow rate of the impeller.

**5.** The humidifier of claim **1**, wherein the housing includes an inner wall, an outer wall and an air gap between the inner and outer walls, the inner and outer walls including at least one vent, and wherein the fan is disposed adjacent to the vent disposed in the outer wall so as to draw air into the gap.

**6.** The humidifier of claim **1**, further comprising a cover disposed over the open top portion configured to allow air and water to pass therethrough.

**7.** The humidifier of claim **6**, further comprising stones disposed on the cover.

**8.** The humidifier of claim **1**, wherein the at least one motor includes a motor having a magnetic drive coupled to the impeller.

**9.** The humidifier of claim **8**, wherein the motor is also coupled to the fan.

**10.** The humidifier of claim **1**, wherein the overflow chamber includes an overflow opening which is open to the main water reservoir.

**11.** The humidifier of claim **1**, wherein the main water reservoir includes a shut-off device.
